# Depth

In many cases, the same information may be organized in different ways, making it more or less useful for various computational purposes. The notion of *depth* was introduced by Bennett as an attempt to separate useful and organized information from random noise and trivial information.

### Definition 1.

A set X is *deep* if, for every computable time-bound t and  $c \in \mathbb{N}$ ,

$$\begin{pmatrix} \stackrel{\infty}{\forall} n \end{pmatrix} \left[ K^t(X \upharpoonright n) - K(X \upharpoonright n) \ge c \right].$$

Otherwise, we say that X is *shallow*.

### Fact.

- The halting problem  $\emptyset'$  is deep.
- If a set is ML-random or computable, then it is shallow.
- (Slow Growth Law) If X is deep and  $X \leq_{tt} Y$ , then Y is deep.

Lower-semicomputable discrete semimeasures

## Definition 2.

- A discrete semimeasure is a function m : 2<sup><ℕ</sup> → [0,∞) such that ∑<sub>σ</sub> m(σ) ≤ 1. It is lower-semicomputable if it is approximable from below. We will write *lss* for lower-semicomputable discrete semimeasure.
- A lss m is universal if, for each lss m,

$$(\forall \sigma) \left[ m(\sigma) \leq^{\times} \mathbf{m}(\sigma) \right].$$

### Fact (Coding Theorem).

There exists a universal lss **m**. In particular,  $\sigma \mapsto 2^{-K(\sigma)}$  is a universal lss. Hence,

$$K(\sigma) =^+ -\log \mathbf{m}(\sigma).$$

< 回 > < 三 > < 三 >

# Depth in terms of discrete semimeasures

It is often convenient to use the following equivalent characterization of depth in terms of discrete semimeasures.

A set X is deep if and only if, for every computable time-bound t,

$$\lim_{n\to\infty}\frac{\mathbf{m}(X\restriction n)}{\mathbf{m}^t(X\restriction n)}=\infty.$$

or equivalently, iff for every computable semimeasure m,

$$\lim_{n\to\infty}\frac{\mathsf{m}(X\restriction n)}{\mathsf{m}(X\restriction n)}=\infty.$$

# Relativized depth

Both the unbounded and the *t*-time-bounded prefix-free complexities of a string  $\sigma$  relative to an oracle A, denoted, respectively, by  $K^{A}(\sigma)$  and  $K^{A,t}(\sigma)$  are defined analogously to the unrelativized case.

The relativized notion of depth is meant to better understand the power of oracles in organizing information.

#### **Definition 3.**

Given an oracle A, we say that a set X is A-deep if, for every computable time-bound t and  $c \in \mathbb{N}$ ,

$$\begin{pmatrix} \stackrel{\infty}{\forall} n \end{pmatrix} \left[ K^{A,t}(X \upharpoonright n) - K^{A}(X \upharpoonright n) \geq c \right].$$

Otherwise, we say that X is A-shallow.

The main properties of depth mentioned above relativize.

< □ > < 同 > < 回 > < 回 > < 回 >

# When depth and relativized depth are incomparable: the case of $\emptyset^\prime$

For some oracles, depth and relativized depth are incomparable. An example is given by the halting problem  $\emptyset'$ . Clearly,  $\emptyset'$  is  $\emptyset'$ -shallow.

Moreover, we can build a ML-random (hence shallow) but  $\emptyset'$ -deep set. In order to do so, we need the following technical lemma (basically, a rephrasing of the Space Lemma (Gács, 1986 and Merkle and Mihailović, 2004)).

#### Lemma 4.

Let  $I(n) \geq^+ \log n$  be a computable function. There exists a  $\Delta_2^0$  perfect tree T such that:

- every string at level n of T has length I(n);
- every infinite path of T is ML-random.

Moreover, if  $l(n) \ge^+ n^2$ , then every string at level n of T has at least  $2^{n+1}$  children.

A (10) < A (10) </p>

When depth and relativized depth are incomparable: the case of  $\emptyset'$  (continue)

#### Theorem 5.

There exists a  $\Delta_2^0$  set X which is ML-random and  $\emptyset'$ -deep.

**Proof (Sketch)**. Let T be a tree as in Lemma 4 and  $F \leq_T \emptyset'$  dominate every computable time-bound.

There exists a path  $(\tau_n)_n \subset T$  such that, for almost all n,  $\mathcal{K}^{\emptyset',F}(\tau_n) \geq n$ , as every string  $\sigma$  at level n-1 has at least  $2^n$  children. Let  $X = \bigcup_n \tau_n$ . Being a path of T, X is ML-random, hence shallow. Moreover, X is  $\Delta_2^0$ , hence, for almost all n,  $\mathcal{K}^{\emptyset'}(X \upharpoonright n) \leq 2 \log n$ . Then, for  $n^2 < m \leq (n+1)^2$ ,

$$\mathcal{K}^{\emptyset',\mathcal{F}}(X\restriction m) - \mathcal{K}^{\emptyset'}(X\restriction m) \geq n - 8\log n,$$

which is eventually larger than any constant. This shows that X is  $\emptyset'$ -deep, as F is dominating.

(a)

## Deep sets remain deep relative to ML-random oracles

There are also oracles which do not make any deep set shallow relatively to them. We show that this is the case for ML-random oracles. We will make use of the following characterization of ML-randomness.

## Definition 6.

 $\Psi: \mathbf{2}^{\mathbb{N}} \rightarrow [0,\infty]$  is an integral test if

- $\Psi$  is *lower-semicomputable*, i.e. the supremum of a computable sequence of computable functions  $\Psi_n : \mathbf{2}^{\mathbb{N}} \to [0, \infty)$ , and
- $\int_{\mathbf{2}^{\mathbb{N}}} \Psi d\mu \leq 1.$

#### Fact.

X is not ML-random if and only if there is an integral test  $\Psi$  such that  $\Psi(X) = \infty$ .

イロト イヨト イヨト イヨト

# Deep sets remain deep relative to ML-random oracles (continue)

#### Theorem 7.

Let A be ML-random. If a set X is deep, then X is also A-deep.

**Proof's sketch.** We prove more: if A is ML-random, then, for every computable time-bound t, there is a computable time-bound t' with

$$(\forall \sigma) \left[ \mathcal{K}^{t'}(\sigma) - \mathcal{K}(\sigma) \leq^{+} \mathcal{K}^{\mathcal{A},t}(\sigma) - \mathcal{K}^{\mathcal{A}}(\sigma) \right].$$
 (†)

The map  $\sigma \mapsto \int_{\mathbf{2}^N} \mathbf{m}^{A,t}(\sigma) d\mu$  is a computable discrete semimeasure. Hence,

$$\int_{\mathbf{2}^{\mathbb{N}}} \mathbf{m}^{\mathbf{A},t}(\sigma) d\mu \leq^{\times} \mathbf{m}^{t'}(\sigma),$$

for some computable time-bound t'.

# Deep sets remain deep relative to ML-random oracles (continue)

**Proof's sketch (continue).** Consider the map  $\Psi : \mathbf{2}^{\mathbb{N}} \to [0,\infty]$  given by

$$\Psi(A) = \sum_{\sigma} \frac{\mathbf{m}^{A,t}(\sigma)\mathbf{m}(\sigma)}{\mathbf{m}^{t'}(\sigma)}.$$

 $\Psi$  is lower-semicomputable and, being only lss involved,  $\int_{\mathbf{2}^{\mathbb{N}}} \Psi d\mu \leq 1$ . Then  $\Psi$  is an integral test.

So, if A is ML-random,  $\Psi(A) < c$ , for some c. But then the map

$$\sigma \mapsto \frac{\mathbf{m}^{A,t}(\sigma)\mathbf{m}(\sigma)}{\mathbf{m}^{t'}(\sigma)}$$

is an A-lss. Then, for any string  $\sigma$ ,

$$\frac{\mathsf{m}^{A,t}(\sigma)\mathsf{m}(\sigma)}{\mathsf{m}^{t'}(\sigma)} \leq^{\times} \mathsf{m}^{A}(\sigma),$$

which implies (†) by the Coding Theorem.

Shallow sets remain shallow relatively to almost every oracle

#### Theorem 8.

If X is shallow, then  $\mu(\{A : X \text{ is } A\text{-}deep\}) = 0.$ 

The idea to prove this theorem is that, if t is a computable time-bound such that  $K^t(X \upharpoonright n) =^+ K(X \upharpoonright n)$  i.o., then

$$\lim_{d\to\infty}\mu\left(\left\{Y: \ \begin{pmatrix}\infty\\\forall n\end{pmatrix}\left[\frac{\mathsf{m}^Y(X\upharpoonright n)}{\mathsf{m}^t(X\upharpoonright n)}\geq d\right]\right\}\right)=\lim_{d\to\infty}\mu(\mathcal{L}_d)=0.$$

 $\mathcal{L}_d$  is, in fact, a test for 2-randomness relative to X. Hence, in particular, X remains shallow relatively to every X-2-random oracle.

**Question.** Does every shallow set remain shallow relatively to any *n*-random oracle, for some *n*?

Depth relative to ML-random oracles is strictly weaker than depth

We answer the previous question in the negative.

Theorem 9.

For every ML-random set A, there exist a shallow set X which is A-deep.

Intuitively, the proof of this fact is similar to the one-time pad protocol in cryptography: we can "mix" together some important piece of information x with some random string a we know, so that the output  $x \boxplus a$  still looks important for us (as we can distinguish the added random noise a), while looking random to the others.

# Depth relative to ML-random oracles is strictly weaker than depth (continue)

## Fact (Moser and Stephan, 2017).

There exists a non-empty  $\Pi_1^0$  class consisting of deep sets.

Hence, we can use well-known basis theorems to obtain deep sets with some desired properties.

### Fact (Randomness Basis Theorem).

Let A be ML-random. Every non-empty  $\Pi_1^0$  class contains a set X such that A is X-ML-random.

So, if A is ML-random, there is a deep set X such that A is X-ML-random. Consider the set  $Y = A \boxplus X$ . Y is X-ML-random, as A is, and hence shallow. Moreover, X is deep, hence A-deep. Then, by the relativized version of the Slow Growth Law, Y is A-deep, as  $X \leq_{tt} Y \oplus A$ .

< □ > < 同 > < 回 > < 回 > < 回 >

# Digression: PA-complete degrees are the join of two ML-random degrees

As a consequence of Theorem 9, it is possible to give a short proof of the following result.

### Fact (Barmpalias, Lewis and Ng, 2010).

Every PA-complete degree is the join of two ML-random degrees.

The key point of the proof is the following lemma, whose proof uses techniques due to Kučera and Slaman (2006).

#### Lemma 10.

Let C be a non-empty Medvedev-complete  $\Pi_1^0$  class (i.e., there is a tt-reduction  $\Phi$  such that  $\Phi(X)$  is  $DNC_2$  for every  $X \in C$ ). For every A of PA-complete Turing degree, there exists  $B \in C$  such that  $B \equiv_T A$ .

・ロト ・ 日 ト ・ ヨ ト ・ ヨ ト

Digression: PA-complete degrees are the join of two ML-random degrees (continue)

Since any  $DNC_2$  function is deep, by Theorem 9 we get that the following  $\Pi_1^0$  class is non-empty (for large enough d)

$$\mathcal{C} = \{ \langle A, X, Y \rangle : A \in DNC_2, X \in MLR_d, Y \in MLR_d, X \boxplus Y = A \},\$$

where  $MLR_d = \{X : (\forall n) [K(X \upharpoonright n) \ge n - d]\}$ . Moreover, the first projection witnesses that Lemma 10 applies to our class. Hence, for every B with PA-complete degree there is a triple  $\langle A, X, Y \rangle \in C$  such that  $B \equiv_T \langle A, X, Y \rangle$ . Moreover, since  $A = X \boxplus Y$ , clearly  $B \equiv_T \langle A, X, Y \rangle \equiv_T \langle X, Y \rangle$ .

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

# Shallowness is preserved by K-trivial oracles

Recall that a set A is K-trivial if  $K(A \upharpoonright n) \leq^+ K(n)$  for all n. Nies (2005) proved that a set A is K-trivial if and only if it is *low for* K, namely if  $K(\sigma) \leq^+ K^A(\sigma)$  for every string  $\sigma$ .

Theorem 11.

Let A be K-trivial. Then every shallow set is A-shallow.

**Proof.** Let t be a computable time-bound such that  $K^t(X \upharpoonright n) =^+ K(X \upharpoonright n)$  i.o. Then, for any such n,

$$\mathcal{K}^{\mathcal{A},t}(X \upharpoonright n) \leq^+ \mathcal{K}^t(X \upharpoonright n) =^+ \mathcal{K}(X \upharpoonright n) \leq^+ \mathcal{K}^{\mathcal{A}}(X \upharpoonright n),$$

so that X is A-shallow.

Then depth relative to K-trivial oracles is either strictly stronger than or equal to depth.

**Open question**. Which of the above possibilities do actually happen? Do all *K*-trivial oracles yield the same answer?
