Outline

- 1 Order Dimension
- 2 Borel order dimension
- 3 A dichotomy
- 4 Locally countable orders

Notation

- \leq is a **quasi order on P** if \leq is a reflexive and transitive relation on P .
- $<$ is a **partial order on P** if $<$ is an irreflexive and transitive relation on P .
- A quasi order \leq on P is **linear** or **total** if for any $x, y \in P$, $x \leq y \vee y \leq x$.
- A partial order $<$ on P is **linear** or **total** if for any $x, y \in P$, $x < y \vee y < x \vee x = y$.
- For a quasi order \leq on P , E_{\leq} is the equivalence relation on P defined by

$$p E_{\leq} q \iff (p \leq q \wedge q \leq p).$$

- For a quasi order \leq , $x < y$ means $x \leq y \wedge y \not\leq x$. $<$ is a partial order. For a partial order $<$, $x \leq y$ means $x < y \vee x = y$. \leq is a quasi order with $E_{\leq} = =$.

- For a quasi order \leq on P , $<$ induces a partial order on P/E_{\leq} , also denoted $<$.
- Example 1: $\mathcal{D} = \langle 2^{\omega}, \leq_T \rangle$, where \leq_T is Turing reducibility.
- Example 2: $\langle \omega^{\omega}, \leq^* \rangle$, where $f \leq^* g$ iff $\forall^{\infty} n \in \omega [f(n) \leq g(n)]$.

Definition

A quasi order $\mathcal{P} = \langle P, \leq \rangle$ is called a **Borel quasi order** if P is a Polish space and \leq is a Borel subset of $P \times P$.

- \mathcal{D} and $\langle \omega^\omega, \leq^* \rangle$ are both Borel quasi orders.

Definition

A quasi order $\mathcal{P} = \langle P, \leq \rangle$ is said to be **locally countable (locally finite)** if for every $x \in P$, $\{y \in P : y \leq x\}$ is countable (finite).

- \mathcal{D} is locally countable.
- $\langle \omega^\omega, \leq^* \rangle$ is not locally countable.

Definition

Suppose \leq_0 and \leq are both quasi orders on P . \leq is said to **extend** \leq_0 if

1 $x \leq_0 y \implies x \leq y$ and

2 $x E_{\leq_0} y \iff x E_{\leq} y,$

for all $x, y \in P$.

If \leq is a linear quasi order which extends \leq_0 , then we say \leq **linearizes** \leq_0 .

- The second condition is saying that P/E_{\leq_0} and P/E_{\leq} are the same.

Definition (Dushnik–Miller [1], 1941)

For a quasi order $\mathcal{P} = \langle P, \leq \rangle$, the **order dimension** (or simply **dimension**) of \mathcal{P} is the smallest cardinality of a collection of linear orders on P/E_{\leq} whose intersection is $<$.

$\text{odim}(\mathcal{P})$ will denote the order dimension of \mathcal{P} .

Fact

The order dimension of \mathcal{P} is the minimal κ such that $\langle P/E_{\leq}, < \rangle$ embeds into a product of κ many linear orders (with the coordinate wise ordering on the product).

- $\text{odim}(\mathcal{P})$ is the minimal κ such that there is a sequence $\langle \leq_i : i \in \kappa \rangle$ of quasi orders on P extending \leq such that for any $x, y \in P$, if $x \not\leq y$, then $y <_i x$, for some $i \in \kappa$.

Elementary facts

- The dimension of a linear order is 1.
- The dimension of an antichain is 2.
- The dimension of a (set-theoretic) tree is 2.
- If \mathcal{P} is an infinite quasi order, then $\text{odim}(\mathcal{P}) \leq |\mathcal{P}|$.
- If $\langle P, \leq \rangle$ embeds into $\langle Q, \leq_0 \rangle$, then $\text{odim}(\langle Q, \leq_0 \rangle) \geq \text{odim}(\langle P, \leq \rangle)$.

Locally finite orders

- If \mathcal{P} is locally finite and $|P| = \kappa$, then \mathcal{P} embeds into $\langle [\kappa]^{<\aleph_0}, \subseteq \rangle$.
- So $\text{odim}(\mathcal{P}) \leq \text{odim}(\langle [\kappa]^{<\aleph_0}, \subseteq \rangle)$.
- $\text{odim}(\langle [\omega]^{<\aleph_0}, \subseteq \rangle)$ is \aleph_0 .
- $\text{odim}(\langle [\omega_1]^{<\aleph_0}, \subseteq \rangle)$ is $\dots \aleph_0$.
- $\text{odim}(\langle [\omega_2]^{<\aleph_0}, \subseteq \rangle)$ is $\dots \aleph_0$.
- $\text{odim}(\langle [\omega_3]^{<\aleph_0}, \subseteq \rangle)$ is \dots
 - 1 if CH and $2^{\aleph_1} = \aleph_2$, then it is \aleph_1 ;
 - 2 else it is \aleph_0 .

Theorem (Kierstead and Milner [5], 1996)

Let $\kappa \geq \omega$ be any cardinal. Then $\text{odim}(\langle [\kappa]^{<\omega}, \subseteq \rangle) = \log_2(\log_2(\kappa))$.

Locally countable orders

Theorem (Higuchi, Lempp, R., and Stephan [3], 2019)

Suppose κ is any cardinal such that $\text{cf}(\kappa) > \omega$ and $\mathcal{P} = \langle P, \leq \rangle$ is any locally countable quasi order of size κ^+ . Then \mathcal{P} has dimension at most κ .

Theorem (Kumar and Raghavan [6], 2020)

$\mathcal{D} = \langle 2^\omega, \leq_T \rangle$ has the largest order dimension among all locally countable quasi orders of size 2^{\aleph_0} .

Theorem (Kumar and Raghavan [6], 2020)

Each of the following is consistent:

- 1 $\aleph_1 < \text{odim}(\mathcal{D}) < 2^{\aleph_0}$;
- 2 $\text{odim}(\mathcal{D}) = 2^{\aleph_0}$ and 2^{\aleph_0} is weakly inaccessible;
- 3 $\text{odim}(\mathcal{D}) = 2^{\aleph_0} = \aleph_{\omega_1}$;
- 4 $\text{odim}(\mathcal{D}) = 2^{\aleph_0} = \aleph_{\omega+1}$.

- Most Borel quasi orders do not have any Borel linearizations.

Definition (Harrington, Marker, and Shelah [2], 1988)

\mathcal{P} is **thin** if there is no perfect set of pairwise incomparable elements.

Theorem (Harrington, Marker, and Shelah [2], 1988)

If $\mathcal{P} = \langle P, \leq \rangle$ is a thin Borel quasi order, then for some $\alpha < \omega_1$, there is a Borel $f : P \rightarrow 2^\alpha$ such that

- 1 $x \leq y \implies f(x) \leq_{\text{lex}} f(y)$ and
- 2 $x E_{\leq} y \iff f(x) = f(y)$, for all $x, y \in P$.

- Hence if $\langle P, \leq_0 \rangle$ is a Borel quasi order and if \leq is a Borel total quasi order extending \leq_0 , then for some $\alpha < \omega_1$, there is a Borel $f : P \rightarrow 2^\alpha$ such that

$$\begin{aligned}x \leq_0 y &\implies x \leq y \implies f(x) \leq_{\text{lex}} f(y) \text{ and,} \\x E_{\leq_0} y &\iff x E_{\leq} y \iff f(x) = f(y),\end{aligned}$$

for all $x, y \in P$.

Definition

On 2^ω , define the partial ordering \leq_0 by $x \leq_0 y$ if and only if $x = y$, or $x E_0 y$ and for the maximal $n \in \omega$ such that $x(n) \neq y(n)$, we have $x(n) < y(n)$.

- E_{\leq_0} is equality and elements in distinct E_0 classes are incomparable.
- The class $[\omega \times \{0\}]_{E_0}$ is linearly ordered in type ω , $[\omega \times \{1\}]_{E_0}$ is linearly ordered in type ω^* , and every other E_0 class is linearly ordered in type \mathbb{Z} by $<_0$.
- If $\langle 2^\omega, \leq_0 \rangle$ were Borel linearizable, then you could find a Borel selector for E_0 , which is impossible.

Theorem (Kanovei [4], 1998)

Suppose $\langle P, \leq \rangle$ is a Borel quasi order. Then exactly one of the following two conditions is satisfied:

- 1 $\langle P, \leq \rangle$ is Borel linearizable;
- 2 there is a continuous 1-1 map $F : 2^\omega \rightarrow P$ such that:
 - (2a) $a \leq_0 b \implies F(a) \leq F(b)$ and
 - (2b) $a \not\leq_0 b \implies F(a)$ and $F(b)$ are \leq -incomparable.

Borel order dimension

Definition

Suppose $\mathcal{P} = \langle P, \leq \rangle$ is a Borel quasi order. The **Borel order dimension** of \mathcal{P} , denoted $\text{odim}_B(\mathcal{P})$, is the minimal κ such that there is a sequence $\langle \leq_i : i \in \kappa \rangle$ of Borel quasi orders on P extending \leq such that for any $x, y \in P$, if $x \not\leq y$, then $y <_i x$, for some $i \in \kappa$.

Definition

Let X be a set and R a binary relation on X that is disjoint from the diagonal. An **R -loop** is a finite sequence $x_0, \dots, x_k \in X$ so that $(x_i, x_{i+1}) \in R$ for all $i < k$, $(x_k, x_0) \in R$.

Definition

Let $\mathcal{X} = \langle X, R \rangle$ be a structure as in the previous definition. The **loop-free chromatic number of \mathcal{X}** , denoted $\mathcal{H}(\mathcal{X})$, is the minimal κ such that $X = \bigcup_{\lambda < \kappa} X_\lambda$, where no X_λ contains an R -loop.

If X is a Polish space and R is a Borel binary relation on X that is disjoint from the diagonal, then the **Borel loop-free chromatic number of \mathcal{X}** , denoted $\mathcal{H}_B(\mathcal{X})$, is the minimal κ such that $X = \bigcup_{\lambda < \kappa} X_\lambda$, where each X_λ is a Borel set that does not contain any R -loops.

- Suppose $\mathcal{P} = \langle P, \leq \rangle$ is a quasi order. Let $\mathcal{A}_{\mathcal{P}} = (P \times P) \setminus \geq$ and define $\mathcal{R}_{\mathcal{P}}$ on $\mathcal{A}_{\mathcal{P}} \times \mathcal{A}_{\mathcal{P}}$ by $(p_0, q_0) \mathcal{R}_{\mathcal{P}} (p_1, q_1) \iff q_0 \leq p_1$.
- $\mathcal{R}_{\mathcal{P}}$ is disjoint from the diagonal because for any $(p, q) \in \mathcal{A}_{\mathcal{P}}$, $q \not\leq p$.
- Suppose $\kappa = \text{odim}(\mathcal{P})$ and that $\langle \leq_{\lambda} : \lambda < \kappa \rangle$ is a witness.
- Let $X_{\lambda} = \leq_{\lambda} \setminus \geq$. Then $\mathcal{A}_{\mathcal{P}} = \bigcup_{\lambda < \kappa} X_{\lambda}$.
- If $(p_0, q_0), \dots, (p_k, q_k)$ is an $\mathcal{R}_{\mathcal{P}}$ -loop in X_{λ} , then $p_0 E_{\leq_{\lambda}} q_0$, which implies $p_0 E_{\leq} q_0$, which is impossible as $q_0 \not\leq p_0$.
- Hence $\mathcal{H}(\langle \mathcal{A}_{\mathcal{P}}, \mathcal{R}_{\mathcal{P}} \rangle) \leq \text{odim}(\mathcal{P})$.

- Conversely suppose $\mathcal{H}(\langle \mathcal{A}_\mathcal{P}, \mathcal{R}_\mathcal{P} \rangle) = \kappa$ and that $\langle X_\lambda : \lambda < \kappa \rangle$ is a witness.
- Let \leq_λ be the transitive closure of $\leq \cup X_\lambda$.
- \leq_λ is then a quasi order on P and $\leq \subseteq \leq_\lambda$.
- $E_{\leq_\lambda} = E_\lambda$ because X_λ is $\mathcal{R}_\mathcal{P}$ -loop free.
- For example, if $pX_\lambda qX_\lambda rX_\lambda p$, then $(p, q), (q, r), (r, p)$ would be an $\mathcal{R}_\mathcal{P}$ -loop in X_λ .
- Similarly if $p \leq qX_\lambda rX_\lambda s \leq tX_\lambda p$, then $(q, r), (r, s), (t, p)$ is an $\mathcal{R}_\mathcal{P}$ -loop in X_λ .
- If $q \not\leq p$, then $(p, q) \in \mathcal{A}_\mathcal{P} = \bigcup_{\lambda < \kappa} X_\lambda$. So $p \leq_\lambda q$, and since $E_{\leq_\lambda} = E_\leq$, $p <_\lambda q$.
- Hence $\text{odim}(\mathcal{P}) \leq \mathcal{H}(\langle \mathcal{A}_\mathcal{P}, \mathcal{R}_\mathcal{P} \rangle)$
- Conclusion: $\text{odim}(\mathcal{P}) = \mathcal{H}(\langle \mathcal{A}_\mathcal{P}, \mathcal{R}_\mathcal{P} \rangle)$.

Theorem (R. and Xiao [7])

If \mathcal{P} is a Borel quasi order, then $\text{odim}_B(\mathcal{P}) = \mathcal{H}_B(\langle \mathcal{A}_{\mathcal{P}}, \mathcal{R}_{\mathcal{P}} \rangle)$.

- Suppose $s = \langle n_k : k \in \omega \rangle \in \omega^\omega$ is such that $n_k \geq 2$ and $n_k \leq n_{k+1}$, for all $k \in \omega$.
- Define $T(s) = \prod_{k \in \omega} n_k$. Let D be a dense subset of $T(s)$ that intersects each level exactly once.
- For $(b_0, b_1) \in [T(s)]$, define $(b_0, b_1) \in R_0(D)$ iff there is a $d \in D$ and an $x \in \omega^\omega$, so that either:

$$b_0 = d \frown \langle i \rangle \frown x \text{ and } b_1 = d \frown \langle i + 1 \rangle \frown x, \text{ or}$$

$$b_0 = d \frown \langle n_{|d|} - 1 \rangle \frown x \text{ and } b_1 = d \frown \langle 0 \rangle \frown x.$$

- Let $\mathcal{G}_0(s, D) = \langle [T(s)], R_0(D) \rangle$.

Definition

$\mathcal{M} = \{M \subseteq 2^\omega : M \text{ is Borel and meager}\}$.

$\text{cov}(\mathcal{M}) = \min \{|\mathcal{F}| : \mathcal{F} \subseteq \mathcal{M} \wedge 2^\omega = \bigcup \mathcal{F}\}$.

Lemma (R. and Xiao [7])

$\mathcal{H}_B(\mathcal{G}_0(s, D)) \geq \text{cov}(\mathcal{M})$.

Proof.

Every Borel non-meager set must contain a loop. □

Theorem (R. and Xiao [7])

Suppose X is Polish $R \subseteq X \times X$ is Borel and disjoint from the diagonal.
Then either:

- 1 $\mathcal{H}_B(\langle X, R \rangle) \leq \aleph_0$, or
- 2 there exist s, D , and a continuous homomorphism $f : \mathcal{G}_0(s, D) \rightarrow \langle X, R \rangle$.

Definition

For s and D , define $\mathcal{P}_0(s, D) = \langle [T(s)] \times 2, \leq_0 \rangle$, where $(b_0, i) \leq_0 (b_1, j)$ iff $i = 0, j = 1$, and $(b_0, b_1) \in R_0(D)$.

- Note that $\{((b, 1), (b, 0)) : b \in [T(s)]\} \subseteq \mathcal{A}_{\mathcal{P}_0(s, D)}$.
- Further, $((b, 1), (b, 0)) \mathcal{R}_{\mathcal{P}_0(s, D)} ((b', 1), (b', 0))$ iff $(b, 0) \leq_0 (b', 1)$ iff $b R_0(D) b'$.
- Therefore, there is a copy of $\mathcal{G}_0(s, D)$ inside the structure $\langle \mathcal{A}_{\mathcal{P}_0(s, D)}, \mathcal{R}_{\mathcal{P}_0(s, D)} \rangle$.
- Hence $\text{odim}_B(\mathcal{P}_0(s, D)) \geq \text{cov}(\mathcal{M})$.

Theorem (R. and Xiao [7])

For any Borel quasi order $\mathcal{P} = \langle P, \leq \rangle$ exactly one of the following holds:

- 1 $\text{odim}_B(\mathcal{P}) \leq \aleph_0$.
- 2 There exist s, D , and a continuous $f : [T(s)] \times 2 \rightarrow P$ such that:
 - (2a) $(b_0, 0) \leq_0 (b_1, 1) \implies f((b_0, 0)) \leq f((b_1, 1))$ and
 - (2b) for every $b \in [T(s)]$, $f((b, 0))$ and $f((b, 1))$ are \leq -incomparable.

Corollary (R. and Xiao [7])

For every Borel quasi order \mathcal{P} , $\text{odim}_B(\mathcal{P})$ is either countable or at least $\text{cov}(\mathcal{M})$.

Theorem (R. and Xiao [7])

For every Borel quasi order \mathcal{P} , if $\text{odim}_B(\mathcal{P})$ is countable, then \mathcal{P} has a Borel linearization.

The Turing degrees

- Combining these results with my earlier results with Higuchi, Lempp, and Stephan, we get that $\text{odim}_B(\mathcal{D})$ is usually strictly bigger than $\text{odim}(\mathcal{D})$.
- For example, if $\text{cf}(\kappa) > \omega$, $2^{\aleph_0} = \kappa^+$, and $\text{MA}_\kappa(\text{countable})$ holds. Then $\text{odim}(\mathcal{D}) \leq \kappa < \kappa^+ = \text{cov}(\mathcal{M}) = \text{odim}_B(\mathcal{D})$.
- In particular, if PFA holds, then $\text{odim}(\mathcal{D}) = \aleph_1 < \aleph_2 = \text{odim}_B(\mathcal{D}) = 2^{\aleph_0}$.

Theorem (R. and Xiao [7])

If \mathcal{P} is a locally finite Borel quasi order, then $\text{odim}_B(\mathcal{P}) \leq \aleph_0$.

- Our dichotomy does not provide any natural upper bound on $\text{odim}_B(\mathcal{D})$ other than 2^{\aleph_0} .
- So it is natural to wonder whether $\text{odim}_B(\mathcal{D}) = 2^{\aleph_0}$.

Theorem (R. and Xiao [7])

There is a c.c.c. forcing which forces that for every locally countable Borel quasi order \mathcal{P} , $\text{odim}_B(\mathcal{P}) = \aleph_1$.

- So starting with a ground model \mathbb{V} where $2^{\aleph_0} = \aleph_{17}$, there is a cardinal preserving forcing extension in which $2^{\aleph_0} = \aleph_{17}$ and for every locally countable Borel quasi order \mathcal{P} , $\text{odim}_B(\mathcal{P}) = \aleph_1$.
- Each $\mathcal{P}_0(s, D)$ is locally countable. So in this model, $\mathcal{H}_B(\mathcal{G}_0(s, D)) = \aleph_1 < 2^{\aleph_0}$, for every s and D .
